\textbf{Background and Objective:} Preoperative anxiety has affected many surgical outcomes and the previous study revealed 16% of preoperative patients having an anxiety. Since no report was found in any university hospitals in Thailand. This study aimed: 1) To estimate the proportion of preoperative anxious inpatients. 2) To study the preoperative inpatients reasons of anxiety and 3) To study level of information required.

\textbf{Method:} This was a descriptive study in a university hospital in Northeast of Thailand. The study population comprised of 91 preoperative inpatients that had to undergo to the operation on 27\textsuperscript{th} - 29\textsuperscript{th} October 2014. SPSS-PC v 17 and Epi info were used to analyze and report the following descriptive statistics: frequency, percent and 95% CI, and anxiety will be reported when APAIS-anxiety score \geq 11.

\textbf{Results:} The response rate was 96.7% (88/91). The proportion of preoperative anxiety patients were 34.5%, (95% CI: 24.8, 45.5). The proportion of preoperative inpatients undergone to the major surgery had the higher proportion as compared to those having the minor surgery (43.2% vs 24.4%). The patients thought that the top three reasons causing any preoperative anxiety were their post-operative complications (55.2%), risk of operation (49.4%) and post-operative pain (47.7%), respectively. Interestingly, one-third of informed consent patients acquired more information regarding operations at high strength.

\textbf{Conclusion:} One-third of the preoperative inpatients of a university hospital had the preoperative anxiety. The highest proportion of the reason concerning the cause of pre-operative anxiety was post-operative complications.
